

# Grounding wire of secondary distribution cabinet

## Overview

1 lists the specific size for each current, from a minimum of 15 amps, providing a wire no smaller than 14 AWG (for copper) and 12 AWG (for aluminum). Since there is no current rating smaller than this, these are the smallest acceptable wire sizes for grounding. Grounding is a mechanism to protect distribution equipment and people under normal operating conditions, abnormal operational (overcurrent and overvoltage) responses, and hazardous conditions such as shocks. Grounding is necessary to assure correct operation of electrical devices, to assure safety. Secondary equipment grounding refers to connecting the secondary equipment (such as relay protection and computer monitoring systems) in power plants and substations to the earth via dedicated conductors. Simply put, it establishes an equipotential bonding network, which is then connected to the earth. If you've ever found yourself scratching your head over whether that metal door on your distribution cabinet really needs a grounding wire, you're not alone. In factories, construction sites, and even commercial buildings, this question pops up all the time. Your boss might insist on it, while you might be unsure. The correct wire routing. EMC stands for Electromagnetic Compatibility. However, the idea is always the same - electrical devices are not allowed to interfere with each other. The voltage, system arrangement, loads connected, and continuity of the system are all factors to consider. According to NEC Article 250, both the neutral and ground wires must be connected only in the main panel or at the first service disconnect.
