

Isostatic pressing of ceramic ferrules

Overview

Isostatic pressing uses a powder with very low water content (generally 1%-3%), and it is not necessary or rarely to use adhesives or lubricants. This is advantageous for reducing drying shrinkage and firing shrinkage. There is no big restriction on the size of the part and the ratio. Hot isostatic pressing (HIP) is pivotal in advancing ceramic materials by consolidating and densifying them through high temperature and pressure. This technique significantly improves mechanical, thermal, and electrical properties, resulting in ceramics with enhanced structural integrity and. Selection of uniaxially and isostatically pressed components. The methods of uniaxial and isostatic dry pressing are applied at a high level at IKTS, are constantly developed. Isostatic pressing is also called hydrostatic isostatic pressing. The mold is filled with ceramic powder and immersed in a pressurized fluid, which applies equal pressure to the entire surface of the mold. Another key factor in this process is the optimization of the sintering process, which greatly influences the physical properties of the ceramics.
