

## Optical module transmit and receive connections must be reversed first

### Overview

The transmit/receive flip must happen with the patch cords either at the beginning or end of the link to ensure proper transceiver polarity. This method utilizes a key up to key up position and this fiber cable is fully flipped on either end. Polarity in fiber optic networks refers to the alignment of transmit (Tx) and receive (Rx) signals between interconnected devices. For this signal alignment to work. As data centers strive for higher density and faster 100G/400G speeds, MTP®/MPO multi-fiber connectors have become the go-to solution for reducing cable clutter. In MTP/MPO connectors, which house multiple fibers (typically 8, 12, 24, or more), polarity management is complex due to. Fiber polarity is the direction that light signals travel from one end of a fiber optic cable (link) to the other.
