

Why do optical power meters have large errors

Overview

Each instrument has its own errors, plus we have the errors caused in the transfer process: source wavelength, spectral width and stability, variations caused by the connection to the source over a fiber optic cable (just bending losses are very critical on a lab bench!). Each instrument has its own errors, plus we have the errors caused in the transfer process: source wavelength, spectral width and stability, variations caused by the connection to the source over a fiber optic cable (just bending losses are very critical on a lab bench!). It is important that users of calibrated power meters and detectors understand and take into consideration the total uncertainty or error that exists in their measurements. Often, users assume that the rated calibration uncertainty of the Newport detector or power meter is the only error in their. The total accuracy of measurement of a laser power/energy meter is affected by the following factors: The calibration¹ uncertainty of the measuring sensor at the power level, energy level and wavelength at which it was calibrated. The energy calibration uncertainty, i . It measures only total received optical energy within the detector's acceptance bandwidth. optical power is a necessary condition for link operation, but never a sufficient condition for link health.
